

In order to help you understand the care we have provided; I have prepared this examination report to address the principal features of your eye health and your vision correction requirements.

FLOPPY EYELID SYNDROME

With this condition, the eyelids are softer and more flexible than usual. In many cases, the upper eyelid may even turn inside-out with little or no effort. This condition may make it difficult for the eyelids to close completely, especially during sleep. This causes irritation and dryness to the front tissues of the eye. Generally, patients have red-irritated eyes and mild mucus discharge, which is often worse upon awakening.

Floppy eyelid syndrome may be a result of age changes and/or obesity. Treatment may include lubricants, antibiotics, taping or shielding of lids during sleep and in extreme cases, eyelid-tightening surgery. Patients with this condition may find it helpful to refrain from sleeping face down on their pillow or mattress.

I hope you have found this report interesting and informative. This personalized report has been motivated by my goal to provide excellence in eye care. I look forward to seeing you for your future eye care needs.
